Not illustrated. 1899 Excerpt: . . . time taken to remove the sludge is from three to ten minutes, varying with the size of the tank, and very little power is required to rotate the sludge pipe. The method by which the sewage is let into the tank is also of great importance, inasmuch as it causes the effluent-water to become clear and bright, and in good condition to go to the filters. The chemical which we use, called ferozone, is acknowledged to be the best and most powerful precipitant and deodorant known for sewage purification. It is rich in salts of alumina and salts of iron, both in the ferrous and ferric condition. By virtue of its soluble salts it soon causes subsidence of the suspended solids. Ferozone attacks the molecular constitution of that portion of the organic matters in solution which can not be removed by ordinary precipitation in the settling tanks. It so alters the constitution of these pntrescible matters that further oxidation thereof by filtration through polarite becomes certain, and under complete control at all times. The sludge precipitated by it is richer in ammonia than that produced by the lime or other processes, and is therefore of more value as a fertilizer. Iolarite is successfully used in the filters for purifying the ferozoned sewage water from the putrescible matter which is dissolved therein. Folarite is a black, hard, and highly porous substance, insoluble in water and practically everlasting, and loes not require to be renewed. It is also...
